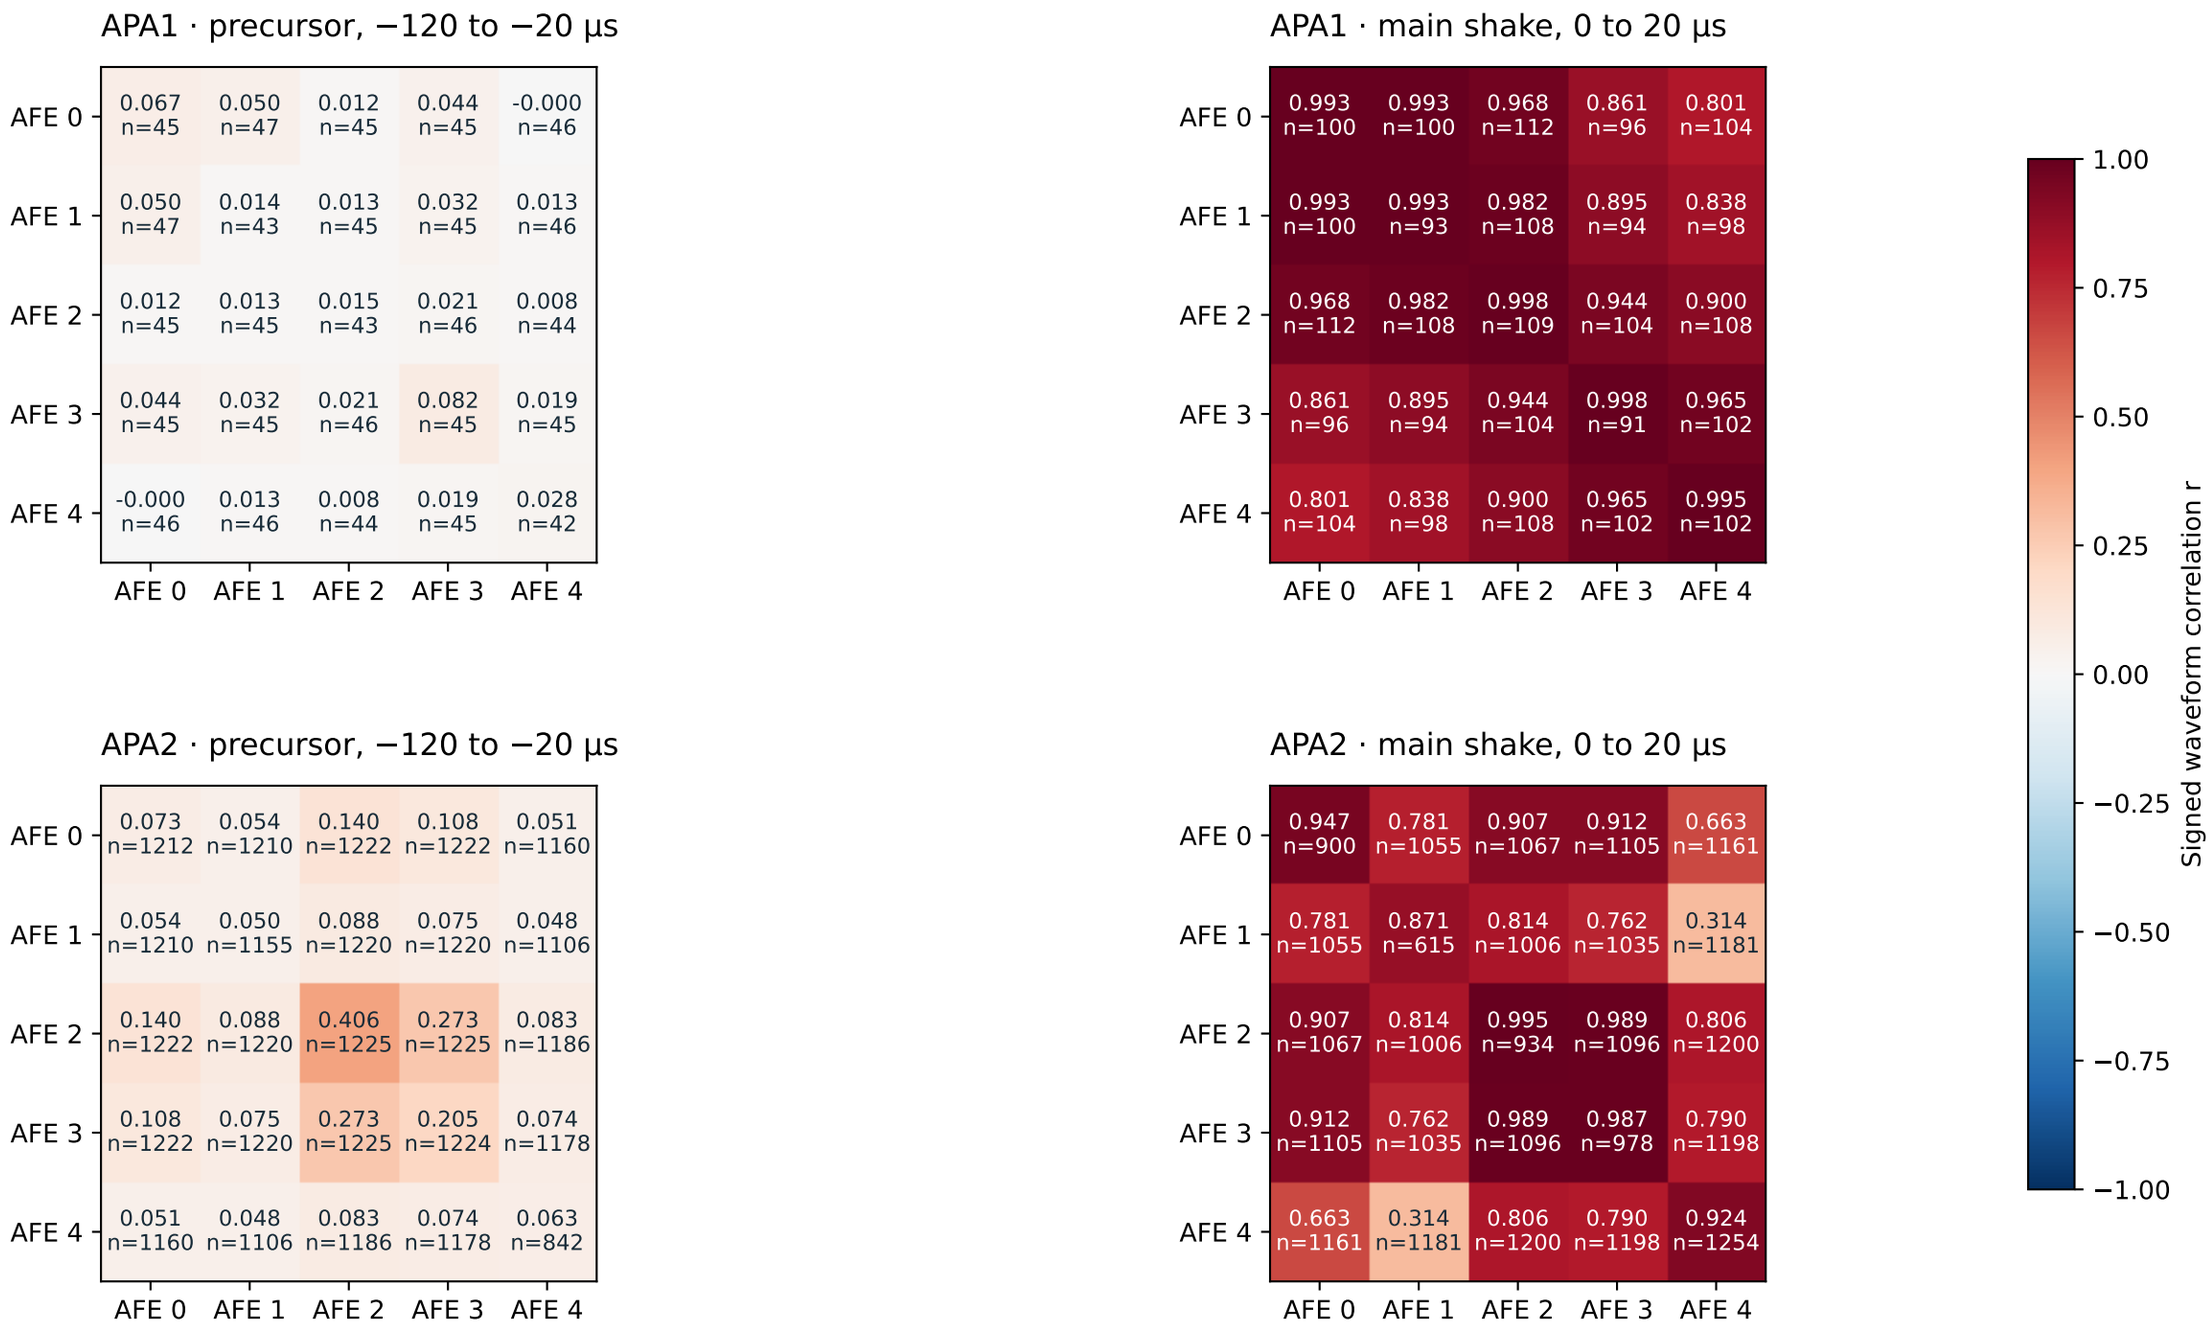
The main shake is shared across AFEs

Each square compares recorded waveforms from the two named AFEs. The precursor correlation is much weaker.



+1: matching shapes. 0: no linear match. −1: inverted shapes. n counts events contributing to that square.

Take the middle correlation across channel pairs within each event, then across events. Diagonal squares compare different inputs on one AFE.

Use common recorded samples in complete 0.512 µs bins. Disconnected APA2 M8 inputs are included in AFE 1.

The two APAs were recorded in different runs. These are correlations within each board, not simultaneous correlations between boards.
