Where the PDS response appears

APA2 · Run 32731, event 52 · DAPHNE 109

One box per channel, in physical module order. Numbers are channel IDs; time 0 is the main-shake marker.

Field-cage corner: top right of every map, beside channel 20.

Each panel has its own colour scale. Signal size is the distance from baseline; pulse sign is ignored.

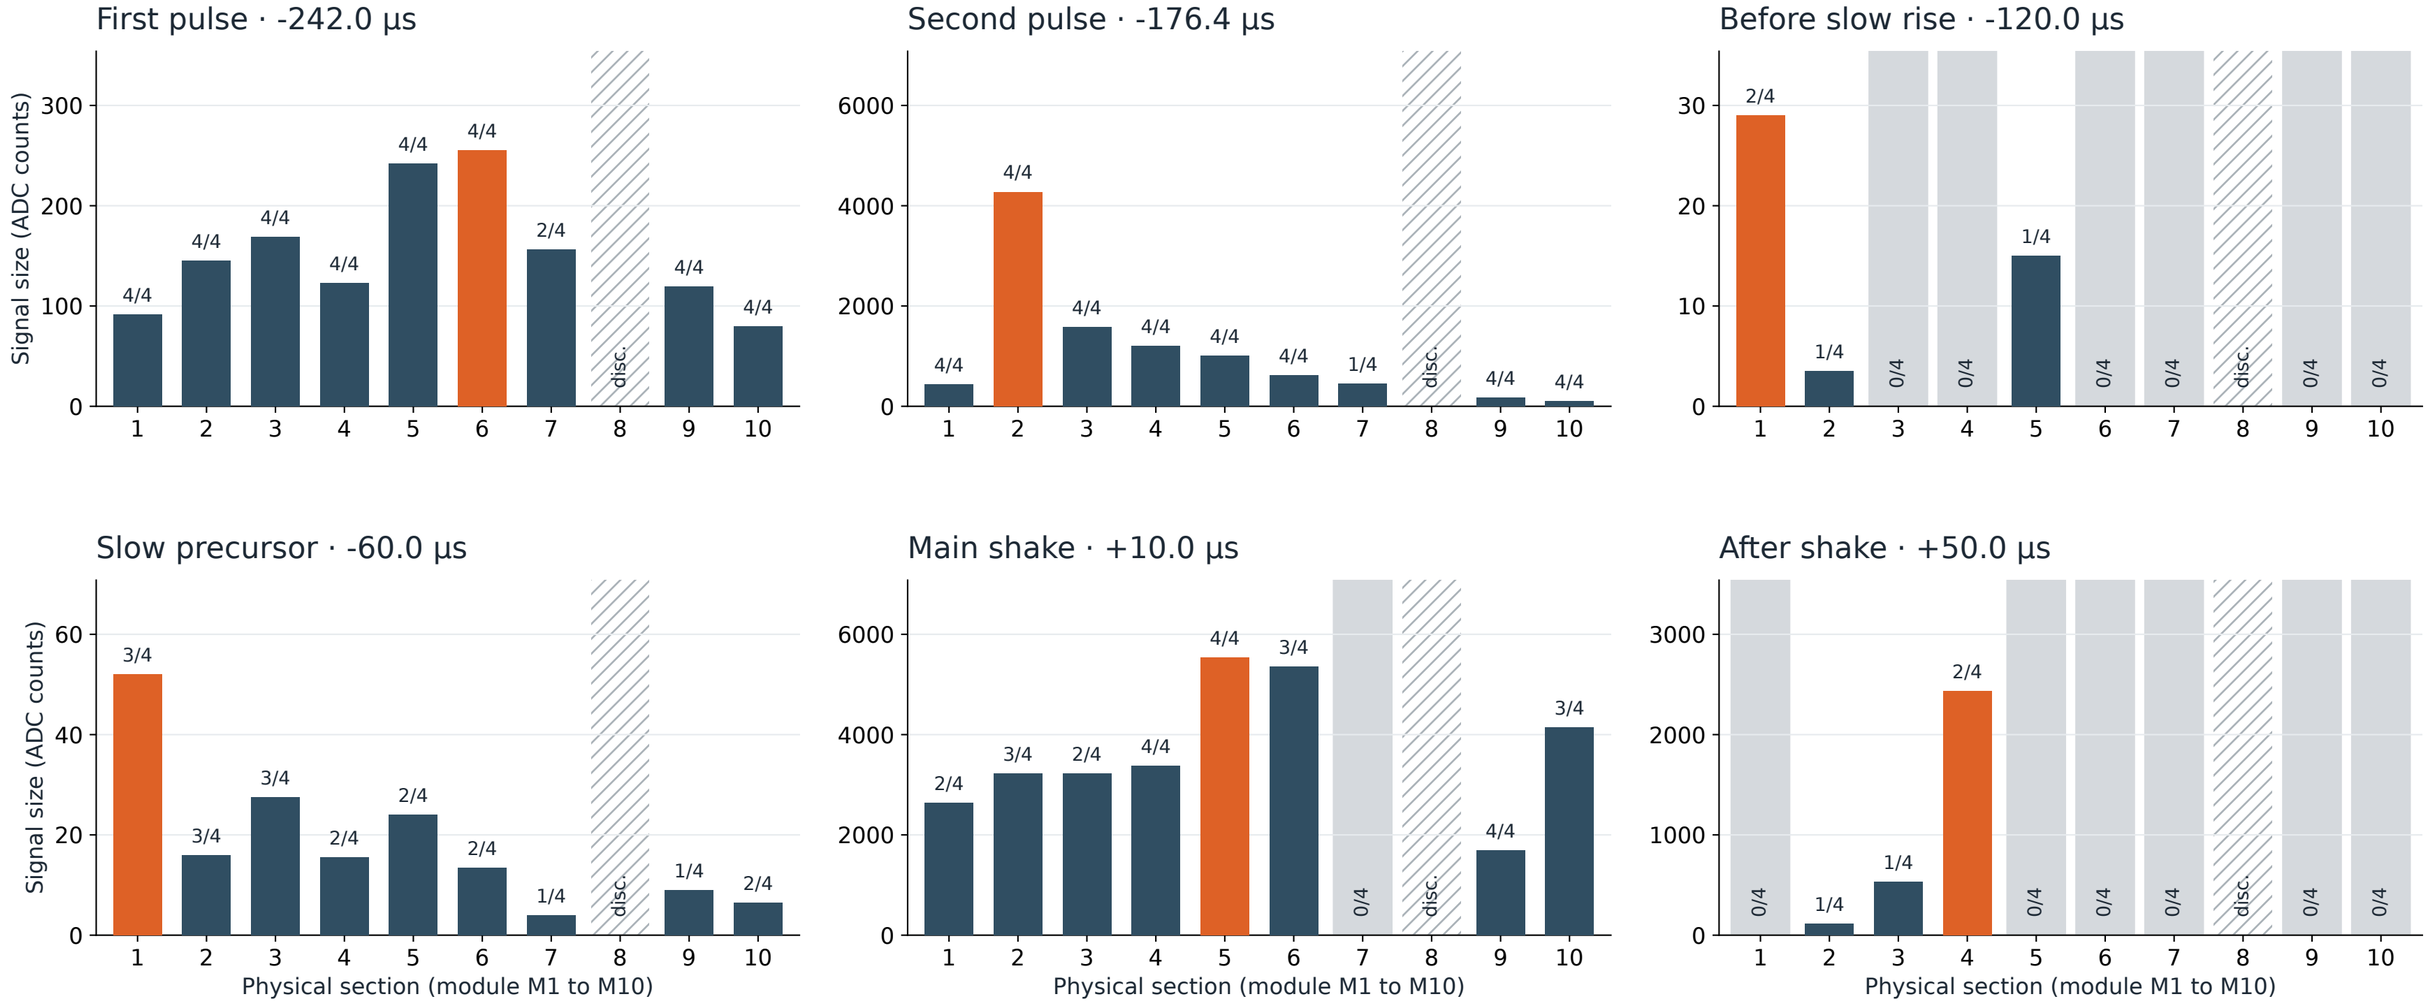

Grey does not mean quiet. Sparse coverage before the slow rise and after the shake prevents a full spatial comparison.

Each snapshot: 0.512 µs. Uncalibrated ADC counts, not photons. Layout: EDMS 3493627 v1, p. 18; not metric coordinates.

Which physical section has the largest recorded signal?

APA2 · Run 32731, event 52 · DAPHNE 109

Each bar is the largest connected-channel signal in that module. Labels give recorded channels out of four.

Compare the bar shapes to see which sections dominate. Vertical scales differ so the small precursor remains visible.

M8 contains the four reported disconnected channels and is shown separately in the channel maps. Grey means no usable channel.

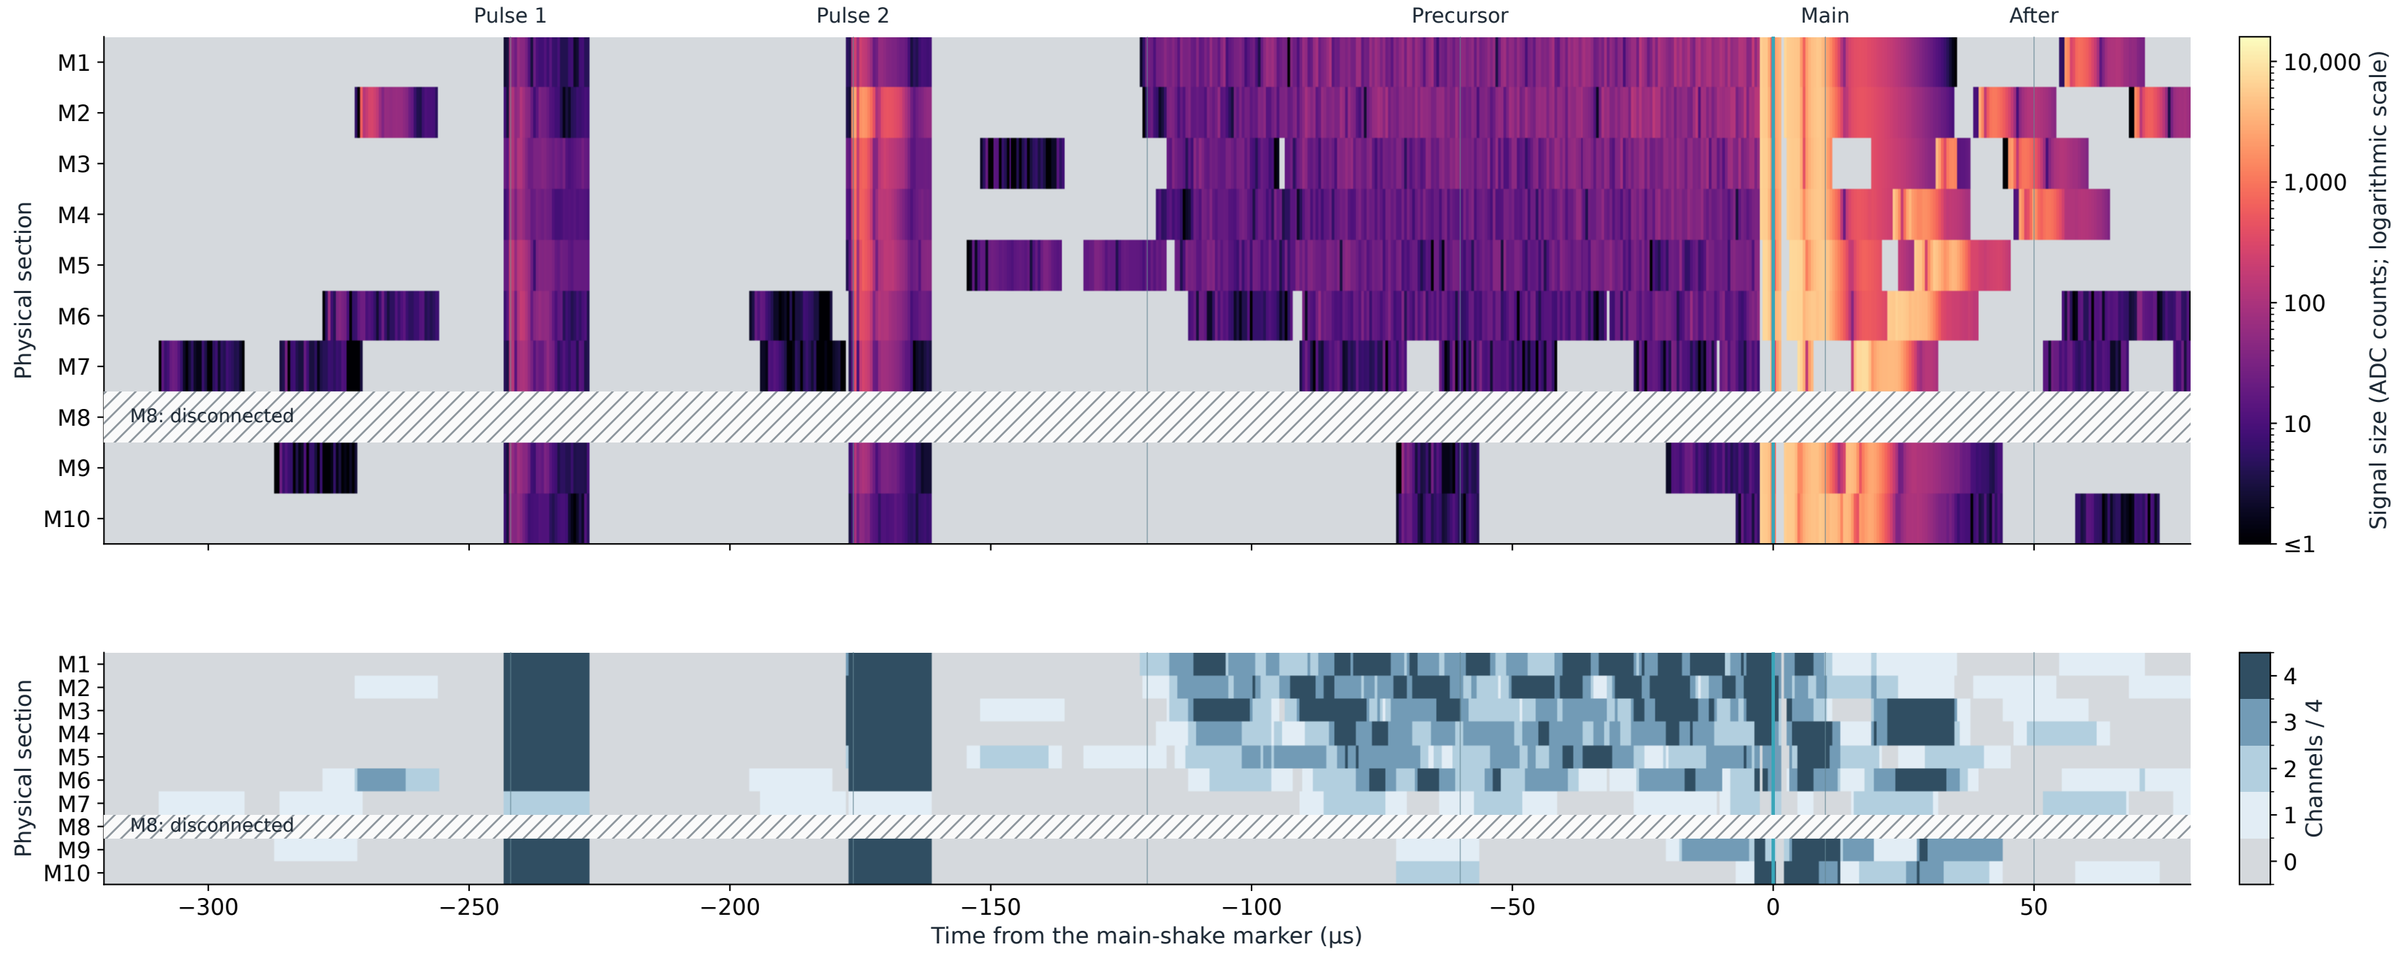

A maximum is not a sum or an integral. Fewer recorded channels can hide a stronger response; these bars do not measure total light.

Module order follows the physical APA2 map. Snapshots are 0.512 µs wide; signal size is |ADC − baseline|.

Follow the recorded response through APA2

APA2 · Run 32731, event 52 · DAPHNE 109

Top: largest connected-channel signal in each physical section. Bottom: channels with usable samples.

Bright bands show large recorded signals. Read them with the coverage panel: a gap cannot show where the signal went.

The colour scale is fixed over time. The logarithmic scale makes both the small precursor and the large shake visible.

These are changes in the recorded spatial pattern, not a measured path of a moving source. ADC counts are not calibrated light.

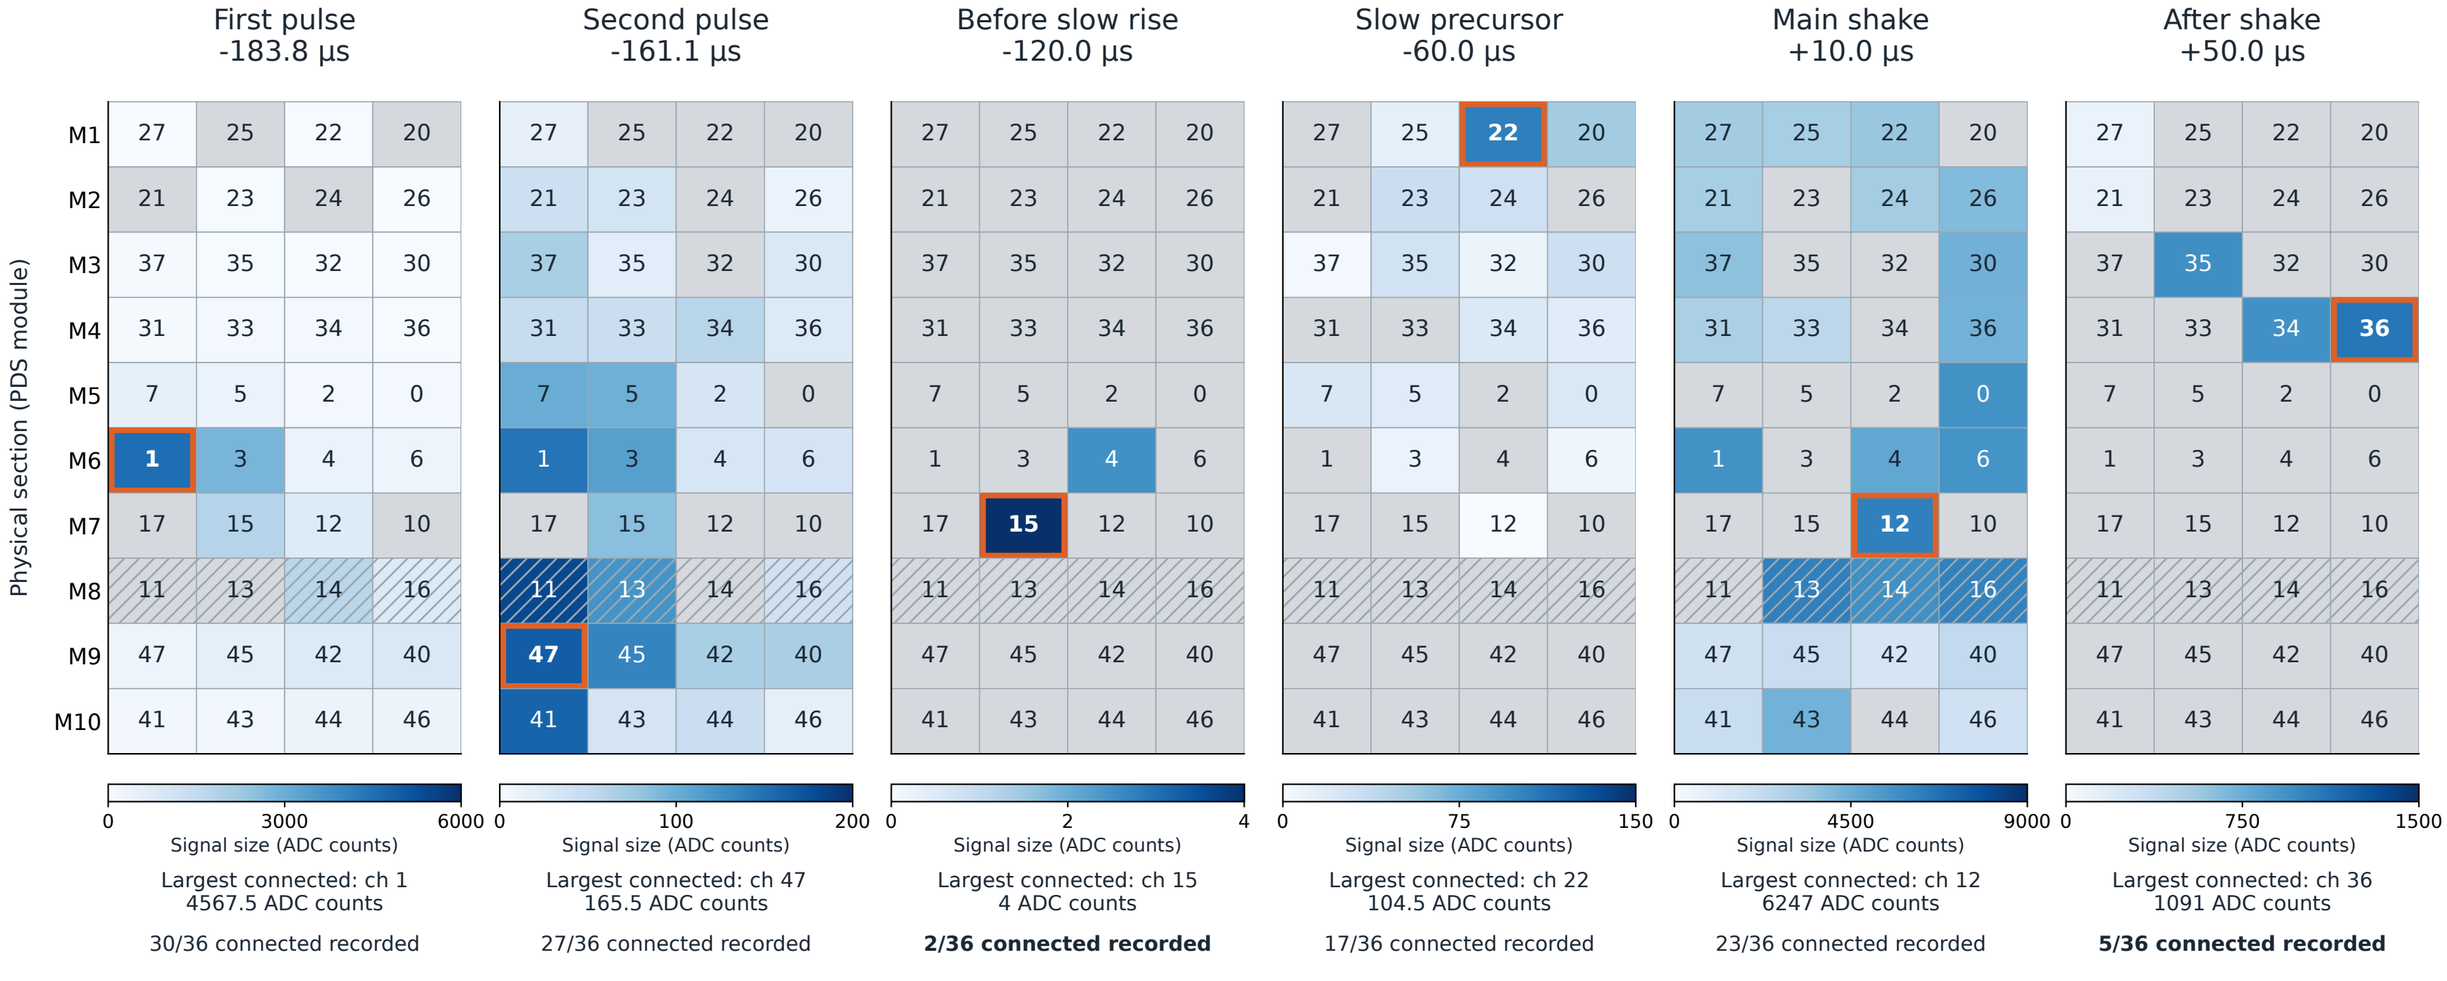

Existing 0.512 µs channel medians; ≥26 of 32 native samples required. No interpolation. Rail-flagged bins excluded.
